Generative Models Discriminative vs Generative

Understanding Machine Learning

Archetype: Naïve Bayes

probabilistic model:

$$P(Y|X_1, \cdots, X_p) = \frac{P(Y, X_1, \cdots, X_p)}{P(X_1, \cdots, X_p)} = \frac{P(Y)P(X_1, \cdots, X_p|Y)}{P(X_1, \cdots, X_p)} \propto P(Y)P(X_1, \cdots, X_p|Y)$$
Bayes' rule constant to be estimated

approach:

- 1. estimate $P(Y, X) \rightarrow$ generative model (can be used to generate new samples)
- 2. calculate P(Y|X) from $P(Y,X) \rightarrow$ used for discriminative task (classification)

Independence Assumption

(naïve) assumption: conditional independence of features given target

$$P(X_j|Y,X_1,\cdots,X_{j-1},X_{j+1},\cdots,X_p) = P(X_j|Y)$$

$$\Rightarrow P(Y|X_1, \dots, X_p) = \frac{P(Y) \prod_{j=1}^p P(X_j|Y)}{P(X_1, \dots, X_p)}$$

- → independent feature contributions (ignoring feature correlations)
- → robust against curse of dimensionality

Estimation of Feature Contributions

separate estimations of $P(X_j|Y)$ for each feature

requires assumption of distributions (e.g., Gaussian naïve Bayes) or non-parametric methods (kernel density estimation)

Gaussian feature likelihoods:

$$P(x_{ij}|y) = \frac{1}{\sqrt{2\pi\sigma_{y,j}^2}} \exp\left(-\frac{(x_{ij}-\mu_{y,j})^2}{2\sigma_{y,j}^2}\right)$$

parameter estimation (e.g., mean and variance of Gaussians) can be done with maximum likelihood method (y known in training)

→ no Bayesian methods needed

Maximum a Posteriori Classification

$$\hat{y}_i = \underset{y}{\operatorname{argmax}} P(y) \prod_{j=1}^p P(x_{ij}|y)$$

despite potentially inaccurate probability estimates (due to naïve independence assumption), good identification of correct class via maximum probability

→ bad for regression tasks (if independence assumption is too naïve, i.e., features are correlated)

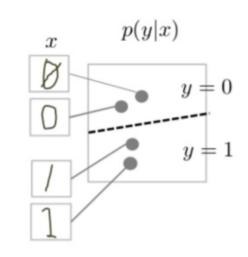

Generative vs Discriminative Models

generative models: predict joint probability P(Y, X) (what allows to create new data samples) or directly generates new data samples

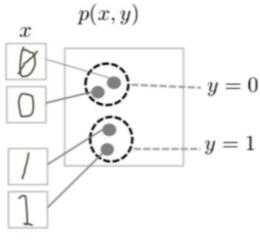

discriminative models: predict conditional probability P(Y|X) or directly output (label for classification, real value for regression)

task of generative models more difficult: model full data distribution rather than merely find patterns in inputs to distinguish outputs

discriminative model

generative model

<u>source</u>

Naïve Bayes and Logistic Regression

generative-discriminative pair of classification algorithms

- binary case: logit of naïve Bayes' outputs, $\log\left(\frac{P(y_i=1|x_i)}{P(y_i=0|x_i)}\right)$, corresponds to output of logistic regression's linear predictor
- for discrete inputs or Gaussian naïve Bayes: naïve Bayes can be reparametrized as linear classifier

for discriminative task: identical in asymptotic limit (infinite training samples) if independence assumption holds (otherwise naïve Bayes less accurate)

naïve Bayes has greater bias but lower variance than logistic regression → to be preferred for scarce training data (if bias, i.e., independence assumption, correct)

Data Generation

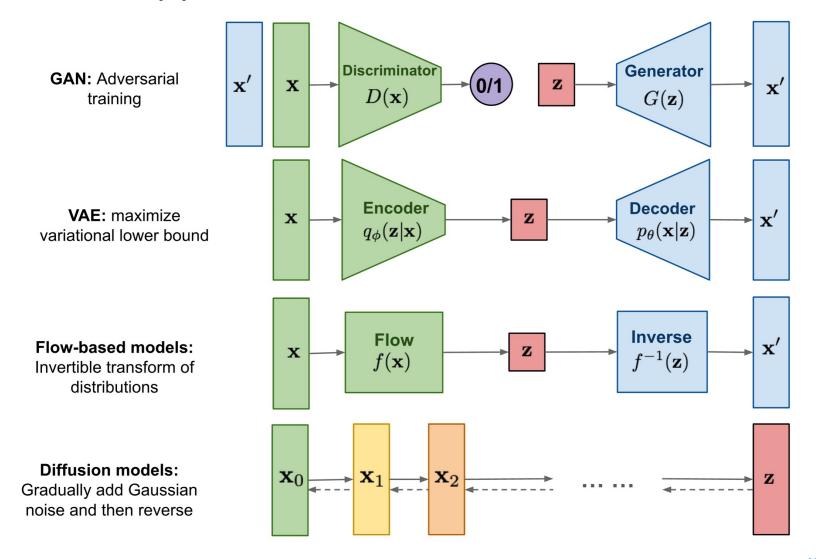

generative models can be used for discriminative tasks (although potentially inferior to direct discriminative methods)

but generative methods do more than discriminative ones: model full data distribution

→ allows generation of new data samples (can be images, text, video, audio, proteins, materials, time series, structured data, ...)

large (auto-regressive) language models examples of generative models

Different Types of Generative Models

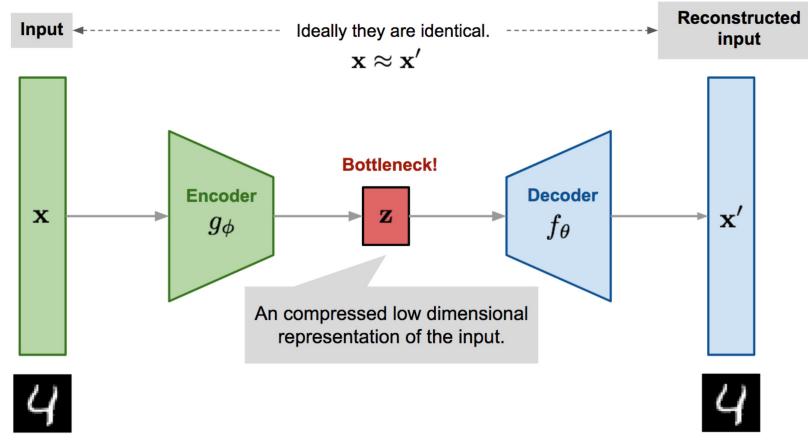

9

Variational Autoencoders (VAE)

Recap: Autoencoder

(deep) encoder network
(deep) decoder network
learned together by
minimizing differences
between original input and
reconstructed input
(expressed as losses)

compressed intermediate representation: dimensionality reduction

source

Autoencoder Architecture for Generative Tasks

goal: generation of variations of input data rather than compressed representation

→ learn variational distribution instead of identity function

to be precise: parametrized variational distribution of latent encoding variables z

prior (simple distribution, in usual VAE:

Gaussian): $p_{\theta}(\mathbf{z})$

posterior:
$$p_{\theta}(\mathbf{z}|\mathbf{x}) = \frac{p_{\theta}(\mathbf{x}|\mathbf{z})p_{\theta}(\mathbf{z})}{\int p_{\theta}(\mathbf{x}|\mathbf{z})p_{\theta}(\mathbf{z})d\mathbf{z}}$$

 $p_{\theta}(x)$: mixture of Gaussians

Input Encoder Space Decoder Output

from wikipedia

Variational Bayesian Method

Encoder and Decoder Networks

encoder: find posterior $p_{\theta}(\mathbf{z}|\mathbf{x})$

unfortunately, generally intractable (integral over **z** expensive)

ightarrow approximate by $q_{m{\phi}}(m{z}|m{x})$

VAE: $q_{\phi}(\mathbf{z}|\mathbf{x})$ expressed by neural network with weights ϕ

 \Rightarrow amortized inference: $q_{\phi}(z|x)$ learned in training, z inferred from x in prediction (sharing variational parameters across all data points)

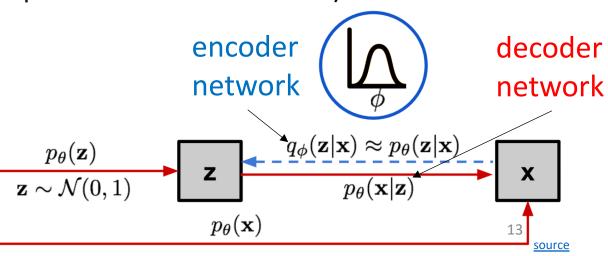

in VAE: network weights $oldsymbol{ heta}$

decoder: generate new sample x_i

- 1. sample z_i (from Gaussian)
- 2. generate x_i (similar to real data)

 \rightarrow maximize: $p_{\theta}(x_i) = \int p_{\theta}(x_i|\mathbf{z}) p_{\theta}(\mathbf{z}) d\mathbf{z}$

(expensive \rightarrow use only likely codes z given input x: need for encoder)

VAE Loss: ELBO

VAE loss function to be minimized according to network weights:

$$L(\boldsymbol{x}_i;\boldsymbol{\theta},\boldsymbol{\phi}) = -\ln p_{\boldsymbol{\theta}}(\boldsymbol{x}_i) + D_{KL} \left(q_{\boldsymbol{\phi}}(\boldsymbol{z}|\boldsymbol{x}_i) || p_{\boldsymbol{\theta}}(\boldsymbol{z}|\boldsymbol{x}_i) \right)$$

maximize likelihood of observed data (minimize reconstruction error)

and

minimize difference of approximation $q_{\phi}(\mathbf{z}|\mathbf{x}_i)$ to exact posterior $p_{\theta}(\mathbf{z}|\mathbf{x}_i)$

14

can be interpreted as regularizer

corresponds to maximizing evidence lower bound (ELBO), i.e., maximizing lower bound of probability to generate real data sample:

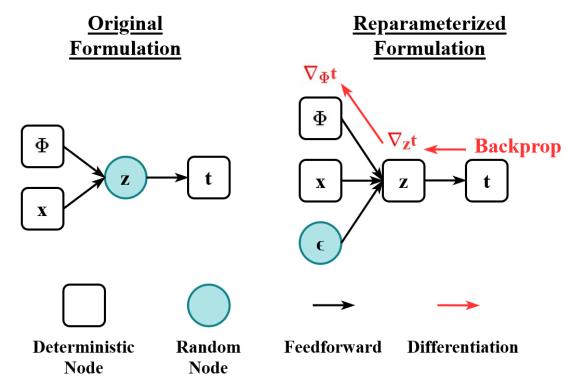

$$\ln p_{\boldsymbol{\theta}}(\boldsymbol{x}_i) \ge \ln p_{\boldsymbol{\theta}}(\boldsymbol{x}_i) - D_{KL} \left(q_{\boldsymbol{\phi}}(\boldsymbol{z}|\boldsymbol{x}_i) || p_{\boldsymbol{\theta}}(\boldsymbol{z}|\boldsymbol{x}_i) \right) = E_{\boldsymbol{z} \sim q_{\boldsymbol{\phi}}(\boldsymbol{z}|\boldsymbol{x}_i)} \left[\ln \frac{p_{\boldsymbol{\theta}}(\boldsymbol{x}_i, \boldsymbol{z})}{q_{\boldsymbol{\phi}}(\boldsymbol{z}|\boldsymbol{x}_i)} \right]$$
non-negative

Reparameterization Trick

 \rightarrow gradient descent according to $m{ heta}$ and $m{\phi}$

issue: not readily possible for ϕ (expecatation over z, which is sampled from q_{ϕ})

 \rightarrow reparametrization to the rescue: express randomness in z by independent auxiliary variable ε

from wikipedia

e.g., q_{ϕ} as multivariate Gaussian with diagonal covariance structure

→ learn mean and variance

from wikipedia

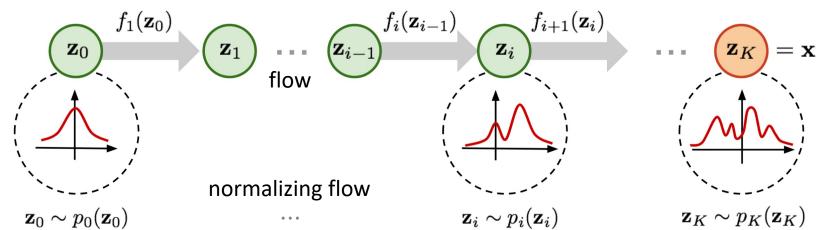

Flow-Based Methods

Normalizing Flows

idea: mapping of a simple probability distribution (often, standard normal distribution) into a complex one by sequence of invertible transformations (repeatedly applying the change-of-variable technique)

$$f(\mathbf{z}') = f(\mathbf{z}) \left| \det \frac{\delta f^{-1}}{\delta \mathbf{z}'} \right| = f(\mathbf{z}) \left| \det \frac{\delta f}{\delta \mathbf{z}} \right|^{-1}$$
$$\ln p_K(\mathbf{z}_K) = \ln p_0(\mathbf{z}_0) - \sum_{k=1}^K \ln \left| \det \frac{\delta f_k}{\delta \mathbf{z}_{k-1}} \right|$$

log-likelihood:

Usage in Generative Models

training: estimate maximum likelihood of normalizing flow (log-likelihood of last slide) by gradient descent (learn parameters θ of transformations f_{θ}^{-1} , e.g., to let $p_0(\mathbf{z})$ be Gaussian)

inference: sample from simple distribution $p_0(\mathbf{z})$ and transform it back to data distribution $p_K(\mathbf{x})$ via f_θ

advantages over VAE:

- instead of simple functions like Gaussians, allow more complex ones: realworld distributions usually much more complicated
- direct/explicit estimation of likelihood (negative log-likelihood as loss): allows density estimation (e.g., to predict rareness of future events)

Invertible Neural Networks

neural networks representing invertible/bijective functions can be used for normalizing flow transformations

need for specialized architectures to construct reversible transform (e.g., affine coupling layers)

Generative Adversarial Networks (GAN)

Indirect Training via Discriminator

two neural networks playing a zero-sum game:

- the generator network G generating new (fake) samples
- the discriminator network D trying to distinguish between real and fake samples

idea: G not trained directly to minimize reconstruction error of real samples, but to fool D \rightarrow self-supervised approach

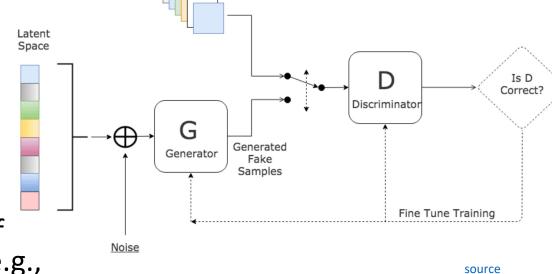

Formulation

common loss for generator and discriminator:

$$L(\boldsymbol{x}_i) = E_{\boldsymbol{x} \sim p_r(\boldsymbol{x})}[\ln D(\boldsymbol{x}_i)] + E_{\boldsymbol{x} \sim p_g(\boldsymbol{x})}[\ln(1 - D(\boldsymbol{x}_i))]$$

- G trying to minimize
- D trying to maximize

decomposition into latent space (parameters of generator network) and noise (sampled from, e.g., Gaussian distribution): reparametrization trick

Properties

implicit generative model: do not estimate likelihood function

for optimal D, GAN loss quantifies similarity between generative data distribution $p_{\it g}$ and real data distribution $p_{\it r}$ by Jensen-Shannon divergence

$$D_{JS}(p||q) = \frac{1}{2} D_{KL}\left(p||\frac{p+q}{2}\right) + \frac{1}{2} D_{KL}\left(q||\frac{p+q}{2}\right)$$

for optimal values of both G and D: $p_g = p_r$ and D = 0.5

issue: potentially unstable training

Diffusion Models

- inspired by non-equilibrium thermodynamics
- Markov chain of diffusion steps to slowly add random noise to data
- ...chain of denoising autoencoders...

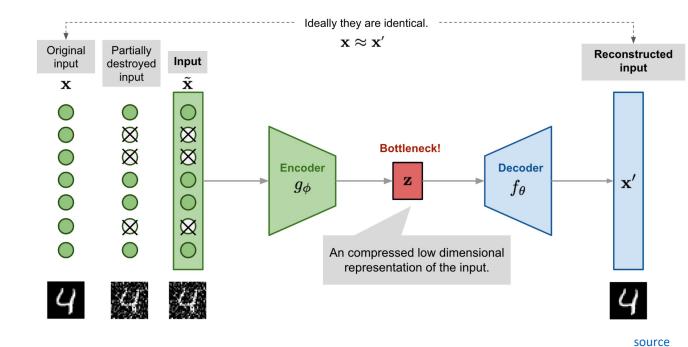

Denoising Autoencoder

goal: avoid overfitting and improve robustness of plain autoencoder

• • •

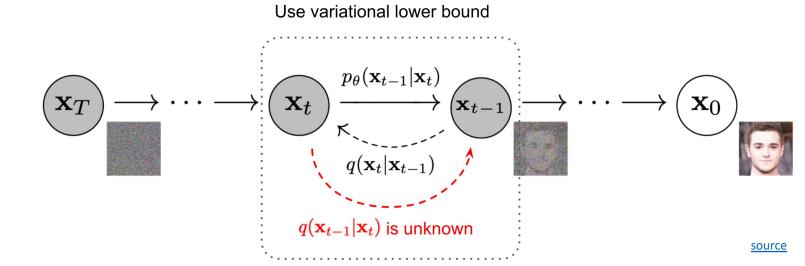

• • •

similar to dropout

- then learn to reverse the diffusion process to construct desired data samples from the noise
- Unlike VAE or flow models, diffusion models are learned with a fixed procedure and the latent variable has high dimensionality (same as the original data).

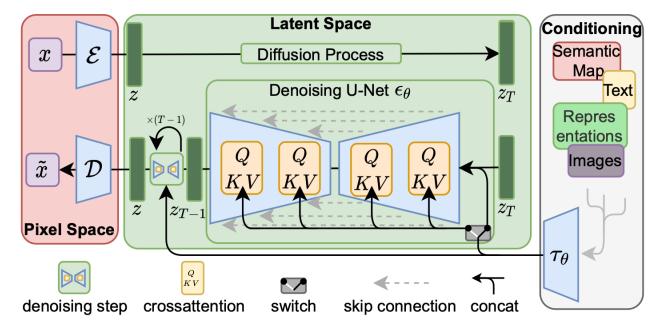

• ...

Latent Diffusion Model

... idea: add noise to latent representation rather than raw data

... speedup

source

Conditioned Generation

as discussed so far, generative methods give no control over what kind of data is generated (limited usability)

> need for conditional approach (e.g., conditioning on describing text)
